Non-Parametric Hypothesis Testing

The following `_bootstrap_` method was introduced in 1979 by Bradley Efron at Stanford University. It was inspired by earlier work on the jackknife. Improved estimates of the variance were [developed later][efron01].

[efron01]: <http://goo.gl/14n8WF> "Bradley Efron & R.J. Tibshirani. An Introduction to the Bootstrap (Chapman & Hall/CRC M

To check if two populations `(y0,z0)_` are different, many times sample with replacement from both to generate `(y1,z1)`, `(y2,z2)`, `(y3,z3)_...` etc.

```

***
def sampleWithReplacement(lst):
    "returns a list same size as lst"
    def any(n): return random.uniform(0,n)
    def one(lst): return lst[ int(any(len(lst))) ]
    return [one(lst) for _ in lst]
***

```

Then, for all those samples, check if some `*testStatistic*` in the original pair hold for all the other pairs. If it does more than (say) 99% of the time, then we are 99% confident in that the populations are the same.

In such a `_bootstrap_` hypothesis test, the `*some property*` is the difference between the two populations, muted by the joint standard deviation of the populations.

```

***
def testStatistic(y,z):
    """Checks if two means are different, tempered
    by the sample size of 'y' and 'z'"""
    tmp1 = tmp2 = 0
    for y1 in y.all: tmp1 += (y1 - y.mu)**2
    for z1 in z.all: tmp2 += (z1 - z.mu)**2
    s1 = (float(tmp1)/(y.n - 1))**0.5
    s2 = (float(tmp2)/(z.n - 1))**0.5
    delta = z.mu - y.mu
    if s1+s2:
        delta = delta/((s1/y.n + s2/z.n)**0.5)
    return delta
***

```

The rest is just details:

- + Efron advises to make the mean of the populations the same (see the `_yhat,zhat_` stuff shown below).
- + The class `_total_` is a just a quick and dirty accumulation class.
- + For more details see [the Efron text][efron01].

```

# different in mu eater by large std
print worker(mu1= 10.1, sigmal= 10,
             mu2= 10.8, sigma2= 1)
***

```

Output:

```

....
_bootstraped()

(1000, 10, 10, 100, 10, 'different')
(1000, 10.1, 1, 10.2, 1, 'same')
(1000, 10.1, 1, 10.8, 1, 'different')
(1000, 10.1, 10, 10.8, 1, 'same')
....

```

Warning-- the above took 8 seconds to generate since we used 1000 bootstraps. As to how many bootstraps are enough, that depends on the data. There are results saying 200 to 400 are enough but, since I am suspicious man, I run it for 1000.

Which means the runtimes associated with bootstrapping is a significant issue. To reduce that runtime, I avoid things like an all-pairs comparison of all treatments (see below: Scott-knott). Also, BEFORE I do the bootstrap, I first run the effect size test (and only go to bootstrapping in effect size passes:

```

***
def different(l1,l2):
    #return bootstrap(l1,l2) and a12(l2,l1)
    return a12(l2,l1) ^ bootstrap(l1,l2)
***

```

Saner Hypothesis Testing

The following code, which you should use verbatim does the following:

- + All treatments are clustered into `_ranks_`. In practice, dozens of treatments end up generating just a handful of ranks.
- + The numbers of calls to the hypothesis tests are minimized:
 - + Treatments are sorted by their median value.
 - + Treatments are divided into two groups such that the expected value of the mean values `_after_` the split is minimized;
- + Hypothesis tests are called to test if the two groups are truly difference.
 - + All hypothesis tests are non-parametric and include (1) effect size tests and (2) tests for statistically significant numbers;
 - + Slow bootstraps are executed if the faster `_A12_` tests are passed;

In practice, this means that the hypothesis tests (with confidence of say, 95%) are called on only a logarithmic number of times. So...

- + With this method, 16 treatments can be studied using less than $\sum_{i=1}^{16} \log_2 i = 15$ hypothesis tests and confidence $0.99 < \sup$
- + But if did this with the 120 all-pairs comparisons of the 16 treatments, we would have total confidence $0.99 < \sup_{i=1}^{120} p_i < 0.30$.
